

Programming Language, Assignment 5

Due: May 27, 11:59 pm

For this assignment, edit a copy of the attached hw5.rkt. In particular, replace occurrences of “CHANGE” to complete the problems. Do not use any mutation (set!, set-mcar!, etc.) anywhere in the homework assignment. Note that we will add more requirements on May 19th. These added requirements take up a large portion of your score of this assignment. You should plan accordingly and be prepared.

Overview

This homework has to do with MUPL (a Made Up Programming Language). MUPL programs are written directly in Racket by using the constructors defined by the structs defined at the beginning of hw5.rkt. This is the definition of MUPL's syntax:

- If *s* is a Racket string, then (var *s*) is a MUPL expression (a variable use).
- If *n* is a Racket integer, then (int *n*) is a MUPL expression (a constant).
- If *e1* and *e2* are MUPL expressions, then (add *e1* *e2*) is a MUPL expression (an addition).
- If *s1* and *s2* are Racket strings and *e* is a MUPL expression, then (fun *s1* *s2* *e*) is a MUPL expression (a function). In *e*, *s1* is bound to the function itself (for recursion) and *s2* is bound to the (one) argument. Also, (fun #f *s2* *e*) is allowed for anonymous nonrecursive function.
- If *e1*, *e2*, *e3* and *e4* are MUPL expressions, then (ifgreater *e1* *e2* *e3* *e4*) is a MUPL expression. It is a conditional where the result is *e3* if *e1* is strictly greater than *e2* else the result is *e4*. Only one of *e3* and *e4* is evaluated.
- If *e1* and *e2* are MUPL expressions, then (call *e1* *e2*) is a MUPL expression (a function call).
- If *s* is a Racket string and *e1* and *e2* are MUPL expressions, then (mlet *s* *e1* *e2*) is a MUPL expression (a let expression where the value resulting *e1* is bound to *s* in the evaluation of *e2*).
- If *e1* and *e2* are MUPL expressions, then (apair *e1* *e2*) is a MUPL expression (a pair-creator).
- If *e1* is a MUPL expression, then (fst *e1*) is a MUPL expression (getting the first part of a pair).
- If *e1* is a MUPL expression, then (snd *e1*) is a MUPL expression (getting the second part of a pair).
- (aunit) is a MUPL expression (holding no data, much like () in ML or null in Racket). Notice (aunit) is a MUPL expression, but aunit is not.
- If *e1* is a MUPL expression, then (isaunit *e1*) is a MUPL expression (testing for (aunit)).
- (closure env *f*) is a MUPL value where *f* is MUPL function (an expression made from fun) and env is an environment mapping variables to values. Closures do not appear in source programs; they result from evaluating functions.

A MUPL value is a MUPL integer constant, a MUPL closure, a MUPL aunit, or a MUPL pair of MUPL values. Similar to Racket, we can build list values out of nested pair values that end with a MUPL aunit. Such a MUPL value is called a MUPL list. You should assume MUPL programs are syntactically correct (e.g., do not worry about wrong things like (int

“hi”) or (int (int 37)). But do not assume MUPL programs are free of type errors like (add (aunit) (int 7)) or (fst (int 7)).

Submission

Write the functions in problem 1 – 4 in a single file, named “sol5.rkt”. Then upload the file to the course homepage (under the assignment 5 menu). Make sure that you test your solution in the repl.

Problems

1. Warm-Up:

- a. Write a Racket function racketlist->mupllist that takes a Racket list (presumably of MUPL values but that will not affect your solution) and produces an analogous MUPL list with the same elements in the same order.
- b. Write a Racket function mupllist->racketlist that takes a MUPL list (presumably of MUPL values but that will not affect your solution) and produces an analogous Racket list (of MUPL values) with the same elements in the same order.

2. Implementing the MUPL Language: Write a MUPL interpreter, i.e., a Racket function eval-exp that takes a MUPL expression e and either returns the MUPL value that e evaluates to under the empty environment or calls Racket’s error if evaluation encounters a run-time MUPL type error or unbound MUPL variable.

A MUPL expression is evaluated under an environment (for evaluating variables, as usual). In your interpreter, use a Racket list of Racket pairs to represent this environment (which is initially empty) so that you can use without modification the provided envlookup function. Here is a description of the semantics of MUPL expressions:

- All values (including closures) evaluate to themselves. For example, (eval-exp (int 17)) would return (int 17), not 17.
- A variable evaluates to the value associated with it in the environment.
- An addition evaluates its subexpressions and assuming they both produce integers, produces the integer that is their sum. (Note this case is done for you to get you pointed in the right direction.)
- Functions are lexically scoped: A function evaluates to a closure holding the function and the current environment.
- An ifgreater evaluates its first two subexpressions to values v1 and v2 respectively. If both values are integers, it evaluates its third subexpression if v1 is a strictly greater integer than v2 else it evaluates its fourth subexpression.
- An mlet expression evaluates its first expression to a value v. Then it evaluates the second expression to a value, in an environment extended to map the name in the mlet expression to v.
- A call evaluates its first and second subexpressions to values. If the first is not a closure, it is an error. Else, it evaluates the closure’s function’s body in the closure’s environment extended to map the function’s name to the closure (unless the name field is #f) and the function’s argument to the result of the second subexpression.
- A pair expression evaluates its two subexpressions and produces a (new) pair holding the results.

- A `fst` expression evaluates its subexpression. If the result for the subexpression is a pair, then the result for the `fst` expression is the `e1` field in the pair.
- A `snd` expression evaluates its subexpression. If the result for the subexpression is a pair, then the result for the `snd` expression is the `e2` field in the pair.
- An `isaunit` expression evaluates its subexpression. If the result is an `aunit` expression, then the result for the `isaunit` expression is the MUPL integer 1, else the result is the MUPL integer 0.

Hint: The `call` case is the most complicated. In the sample solution, no case is more than 12 lines and several are 1 line.

3. **Expanding the Language:** MUPL is a small language, but we can write Racket functions that act like MUPL macros so that users of these functions feel like MUPL is larger. The Racket functions produce MUPL expressions that could then be put inside larger MUPL expressions or passed to `eval-exp`. In implementing these Racket functions, do not use closure (which is used only internally in `eval-exp`). Also do not use `eval-exp` (we are creating a program, not running it).
 - a. Write a Racket function `ifaunit` that takes three MUPL expressions `e1`, `e2`, and `e3`. It returns a MUPL expression that when run evaluates `e1` and if the result is MUPL's `aunit` then it evaluates `e2` and that is the overall result, else it evaluates `e3` and that is the overall result. Sample solution: 1 line.
 - b. Write a Racket function `mlet*` that takes a Racket list of Racket pairs `((s1 . e1) ... (si . ei) ... (sn . en))` and a final MUPL expression `en+1`. In each pair, assume `si` is a Racket string and `ei` is a MUPL expression. `mlet*` returns a MUPL expression whose value is `en+1` evaluated in an environment where each `si` is a variable bound to the result of evaluating the corresponding `ei` for $1 \leq i \leq n$. The bindings are done sequentially, so that each `ei` is evaluated in an environment where `s1` through `si-1` have been previously bound to the values `e1` through `ei-1`.
 - c. Write a Racket function `ifeq` that takes four MUPL expressions `e1`, `e2`, `e3` and `e4` and returns an MUPL expression that acts like `ifgreater` except `e3` is evaluated if and only if `e1` and `e2` are equal integers. Assume none of the arguments to `ifeq` use the MUPL variables `_x` or `_y`. Use this assumption so that when an expression returned from `ifeq` is evaluated, `e1` and `e2` are evaluated exactly once each.
4. **Using the Language:** We can write MUPL expressions directly in Racket using the constructors for the structs and (for convenience) the functions we wrote in the previous problem.
 - a. Bind to the Racket variable `mupl-map` a MUPL function that acts like `map` (as we used extensively in ML). Your function should be curried: it should take a MUPL function and return a MUPL function that takes a MUPL list and applies the function to every element of the list returning a new MUPL list. Recall a MUPL list is `aunit` or a pair where the second component is a MUPL list.
 - b. Bind to the Racket variable `mupl-mapAddN` a MUPL function that takes an MUPL integer `I` and returns a MUPL function that takes a MUPL list of MUPL integers and returns a new MUPL list of MUPL integers that adds `I` to every

element of the list. Use `mupl-map` (a use of `mlet` is given to you to make this easier).
